

BRINGING SEXY BACK

It is time to move past yet another of the half-truth pills that our movement has prescribed to cis/lesb/erosexual society to make our existence easier to swallow.

YOU HAVE NOTHING TO LOSE BUT YOUR AFAB-ONLY HOUSING.

SEIZE YOUR SEX.

We must be quite honest with ourselves — most cisgendered "people" simply **short**hand of perceived sex.

Analysis of the author:

Male (☺)	Female (☺)
Facial hair	Pussy
Baldness	Big-tits
Muscle mass ↑	Snatched waist
Avg. height ↑	Longer hair
Bright feathers	Kissable lips
Mating dances	Milk production
Sperm production	Ova production

- VERDICT: Unclear.**
- Proceeding to manual verification.
 - Big jaw detected. MALE.
 - "SIR" deployed.

Mainstream recognition of transgenderism has come hand-in-hand with a tacit agreement that cis people will consider respecting our genders if, and only if, we concede that our sexes remain unchanged.

Yet in the reasonable abandonment of the world "transsexual" to avoid misunderstandings of it as a sexual orientation, we seem to have also abandoned our "correct" insistence that for many of us, it is not just the socialization of our genders, but the tense and bloody and complex physicality of our sexes that have changed with us.

Our sex characteristics are shaped by genetic, epigenetic, hormonal, and environmental factors. These environmental factors — including mal/nutrition, physical trauma or surgeries, and medications and hormones — help develop and change various sex characteristics through the course of one's life.

Absent any medication, my body currently would produce testosterone on the low range of what doctors measure in cis women, and is completely incapable of producing sperm cells. And on an actual daily basis, my body is dominated by estrogen, and when prescribed a new medication, I am far more likely to experience, and have need to worry about, the side effects documented in Women than in Men. Even with regularly going to the gym, my muscle mass is lower than it was when I was as a high school sophomore. My waist-to-hip ratio is low. I sweat little. I do not grow facial, chest, or abdominal hair; in fact, looking at my chest, it's difficult not to notice my enlarged breasts and nipples.

Countering these are the presence of a thoroughly neuter penis — incapable of sexual reproduction, and which has slowly shifted all of its nerve sensitivity towards the head, more in line with its past as a proto-clitoris in utero. Admittedly, my voice timbre and height are also closer to Male "averages than Female". My face shape I'll let you pull out the callipers for. Yet trans people's biological functions, immune functions, medical risk rates, are documentedly more in line with their new sex than any assigned at birth. A few years after transitioning, I developed symptoms of fibromyalgia; my diagnosis reflected a health condition overwhelmingly found in my newly developed sex. By in large, if we consider the sex characteristics and phenotypic traits of Females "vs Males", the natural answer seems to be "both"; if insisting on a binary, it's difficult to argue that Female's is not more correct, medically.

We understand human sex, then, as loose buckets of biological traits, with some traits assigned more relevance than others. We know empirically that these traits can and do change in many individuals. **FINALLY — MY PRONOUNS ARE SHE/HER!**

If sex is indeed fixed and binary, it is only through its own tautology. Recorded sex is binary because nearly everyone, including intersex people, are forcibly assigned to one category or another at birth and to an according gender, assumed, even if not recorded. And this sex is "fixed" because they insist that it is; sex is unchangeable because sex is the category you were assigned at birth, and well, no way to go back and change what happened when you were born after all! It's in your DNA, which we totally checked, and will check again for the rest of your life!

Biologists, foolishly and without birth certificates to check, would consider sex a category that is identified through observation of individuals' observable sex characteristics -- as an assumption towards other practically-relevant pieces of info that are more difficult to discern like gamete production, hormones, and the presence and non-presence of organs.

Yet it should be clear that the observation of sex characteristics is not a reliable determinant of gamete production, hormones, organ presence, or even DNA makeup. Even if we were to disregard intersex individuals, and look only to infertile people, cis women who are tall or have narrow hips, cis men with gynecomastia, or god forbid, transsexuals — for all of us, sex characteristics are not constant for life, even after puberty. Having a hysterectomy — whether your reason is sex dysphoria, cancer, birth control, fun — changes medical calculus and reproductive capabilities in a way that is not indicated in any way by external sex characteristics, birth certificates, or assumptions.

The average American does not know enough clownfish to tell them that only their gender has changed.

A number of fish species, most popularly clownfish, change their sex, triggered by a need to fill a differing role driven by environmental factors; it is difficult to find any scientists who will deny the truth of this change in sex.
